1 Introduction

1.1 Purpose of Document

The purpose of the document is to collect and analyze all assorted ideas that have come up to define the system, its requirements with respect to consumers. Also, we shall predict and sort out how we hope this product will be used in order to gain a better understanding of the project, outline concepts that may be developed later, and document ideas that are being considered, but may be discarded as the product develops. In short, the purpose of this SRS document is to provide a detailed overview of our software product, its parameters and goals. This document describes the project's target audience and its user interface, hardware and software requirements.

1.2 Intended Audience

The purpose of this document is to give a detailed description of the requirements for our Final year Project. It will illustrate the purpose, scope and complete description for the development of system. It will also explain external interface requirements and system requirements as well as non-functional requirements. This document is primarily intended to be proposed to a customer for its approval and also for further processing such as additions to be developed in later releases. Customers/hospitals can refer to section 3 and 4 for the list of requirements implemented in Version final. This document will also be used as a reference for developing and testing Version final

1.3 Abbreviation

FAQ	Frequently Asked Questions
EHR	Electronic health care Records

1.4 Document Convention

Throughout this document, All the user entities are written in capitalizations i.e., first letter as capital. Also, any significant term which has been described in the glossary is made bold and italic in the text. On the other hand, those terms which are significant (but not described in glossary) are bold in text. The document is prepared using Microsoft Word 2020 and has used the font type 'Times New Roman'. The fixed font size that has been used to type this document is 12pt and for headings 14pt with 1 linespacing

2 Overall System Description

2.1 *Project Background*

Blockchain is also used in the healthcare management system for effective maintenance of electronic health and medical records. The technology ensures security, privacy, and immutability. This work proposes a framework by integrating the blockchain and Federated Deep Learning in order to provide a tailored recommendation system. Electronic medical records contain personal and confidential information that traditional storage methods must protect against cyberattacks and third-party authentication. To overcome this challenge, a method of distributed storage was proposed in this work. The focus of this work is also on making treatment recommendations to patients by comparing their medical records with historical data. This work is motivated by the limitations of existing work. The current study supports his EHR preservation, but the recommendation system is neither discussed nor incorporated, making it difficult to create a treatment recommendation system. Federated learning may therefore lead to more accurate treatment recommendations.

2.2 *Project Scope*

Primarily, the scope of our final year project is limited. We will be limiting our scope to the medical sectors where a patient data will be recorded on our system and by means of recording, we will be using that data only to train our machine learning model. We will be using the concept of federated Learning Through Federated learning, multiple organizations or institutions work together to solve a machine-learning problem under the coordination of a central server or service provide. Thus, a deep-learning model is maintained and improved upon within a central server. The model is trained by distributing itself to hospitals which allows these sites to keep their data localized. Data from each collaborator is never exchanged or transferred during training. Instead of bringing the data to the central server, as in conventional deep learning, the central server maintains a global shared model, which is disseminated to all institutions. Each entity subsequently maintains a separate model based on its own patients' data. Thereafter, each center provides feedback to the server based on its individually trained model—either by its weight or the error gradient of the model. The central server aggregates the feedback from all participants, and based on predefined criteria, updates the global model. The predefined criteria allow the model to evaluate the quality of the feedback and therefore to only incorporate that which is value-adding. The feedback from centers with adverse or strange results can thus be ignored. This process forms one round of federated learning, and it is iterated until the global model is trained.

2.3 *Not In Scope*

We will be only targeting one/two disease for the recommendation and it will be running on local environment not globally deployed. It will be on private blockchain and only people who are connected will have the feasibility to connect to it

2.4 Project Objectives

Our system implementation addresses the three major issues:

1. slow access to medical data
2. system interoperability
3. patient agency

Recent advances in deep learning have shown many successful stories in smart healthcare applications with data-driven insight into improving clinical institutions' quality of care. Excellent deep learning models are heavily data-driven. The more data trained, the more robust and more generalizable the performance of the deep learning model. However, pooling the medical data into centralized storage to train a robust deep learning model faces privacy, ownership, and strict regulation challenges. **Federated learning** resolves the previous challenges with a shared global deep learning model using a central aggregator server. At the same time, patient data remain with the local party, maintaining data anonymity and security.

This method provides decentralized machine learning model training with-out transmitting medical data through a coordinated central aggregate server. Medical institutions, working as client nodes, train their deep learning models locally and then periodically forward them to the aggregate server. The central server coordinates and aggregates the local models from each node to create a global model, then distributes the global model to all the other nodes. It is worth noting that the training data are kept private to each node and never transmitted during the training process. Only the model's weight and parameters are transmitted, ensuring that medical data remain confidential. For these reasons, FL mitigates many security concerns because it retains sensitive and private data while enabling multiple medical institutions to work together. FL holds an excellent promise in healthcare applications to improve medical services for both institutions and patients—for instance, predict autism spectrum disorder, mortality and intensive care unit (ICU) stay-time prediction.

2.5 Stakeholders

Users that will be interacting with our system will be the hospital admin, a super admin and a patient for the development purpose the development team along with the QA team will be responsible for the working of the system and they'll be the one interacting with the system. Stakeholders can only take actions according to the roles providing to them

2.6 Operating Environment

It is a web-based application running on a browser and since it is locally deployed. Only the user with the accessibility can access the system. The user must have a node js version of > 14.00. Ganache should be installed on the system and a web3 provider such as meta mask should be installed on the browser in order to authenticate the system

2.7 *System Constraints*

- **Software constraints**

Node js version above 14.00 for running js locally. Ganache along with meta mask extension should be installed on the system

- **Hardware constraints**

No such constraints for hardware

- **Cultural constraints**

Understanding of English language since all the instructions are provided in English, so we're guessing that our end user should have a good grip on English.

2.8 *Assumption & Dependency*

One assumption about the software is that it will always be used on system that have enough resources to run the application. If the system does not have enough hardware resources available for the application, there may be scenarios where the application does not work as intended or not even at all. The application uses IPFS for online storage of information. If the interface changes the application needs to be adjusted accordingly. External libraries of web3 and ether js should be installed on the system along with the JavaScript, so it should be run smoothly

3 External Interface Requirements

3.1 Hardware Interface

Since the application must run over the internet, all the hardware shall require to connect internet will be hardware interface for the system. As for e.g., Modem, WAN – LAN, Ethernet Cross-Cable.

3.2 Software Interface

Operating System: *We have chosen Windows operating system for its best support and user-friendliness.*

Database: *To save the data of model in an IPFS distributed database system.*

Smart Contracts: *To save and implement the contract which is agreed between two entities in the system*

Ethereum Blockchain: *Ethereum Blockchain used to ensure smoothness of program and decentralization of system*

Global Server: *Global server used to interact with the hospital server to send/receive the training model*

3.3 Communications Interfaces

The DEDOC system shall use the HTTP protocol for communication over the internet and for the intranet communication will be through TCP/IP protocol suite.

4 Functional Requirements

4.1 Functional Hierarchy

The super Admin and providers have a specific identity number that identifies their account. The account is accessed via a special account address of web3 provider such as meta mask and for another way of authentication we will use firebase to authenticate the data. As data will be generated from multiple organizations, data must be accessible and consistent at all times. The integrity of the data must not be compromised.

Features

We have Implemented a user-friendly application user interface using React Js technology. It provides an interactive and responsive UI with adequate performance. The navigation from one page to another is explicitly shown.

The project included the following features with respect to super admin and providers (Healthcare institutions).

Login: Login page for super Admin and provider

Signup: Signup page for provider

functionalities related to provider

View Form: Doctor can view patient available respective data

Fill form: Receptionist will submit the form of the patient

Request a particular doctor: Receptionist can request a particular doctor

Take part in training: provider will have a functionality to train its model

functionalities related to super Admin

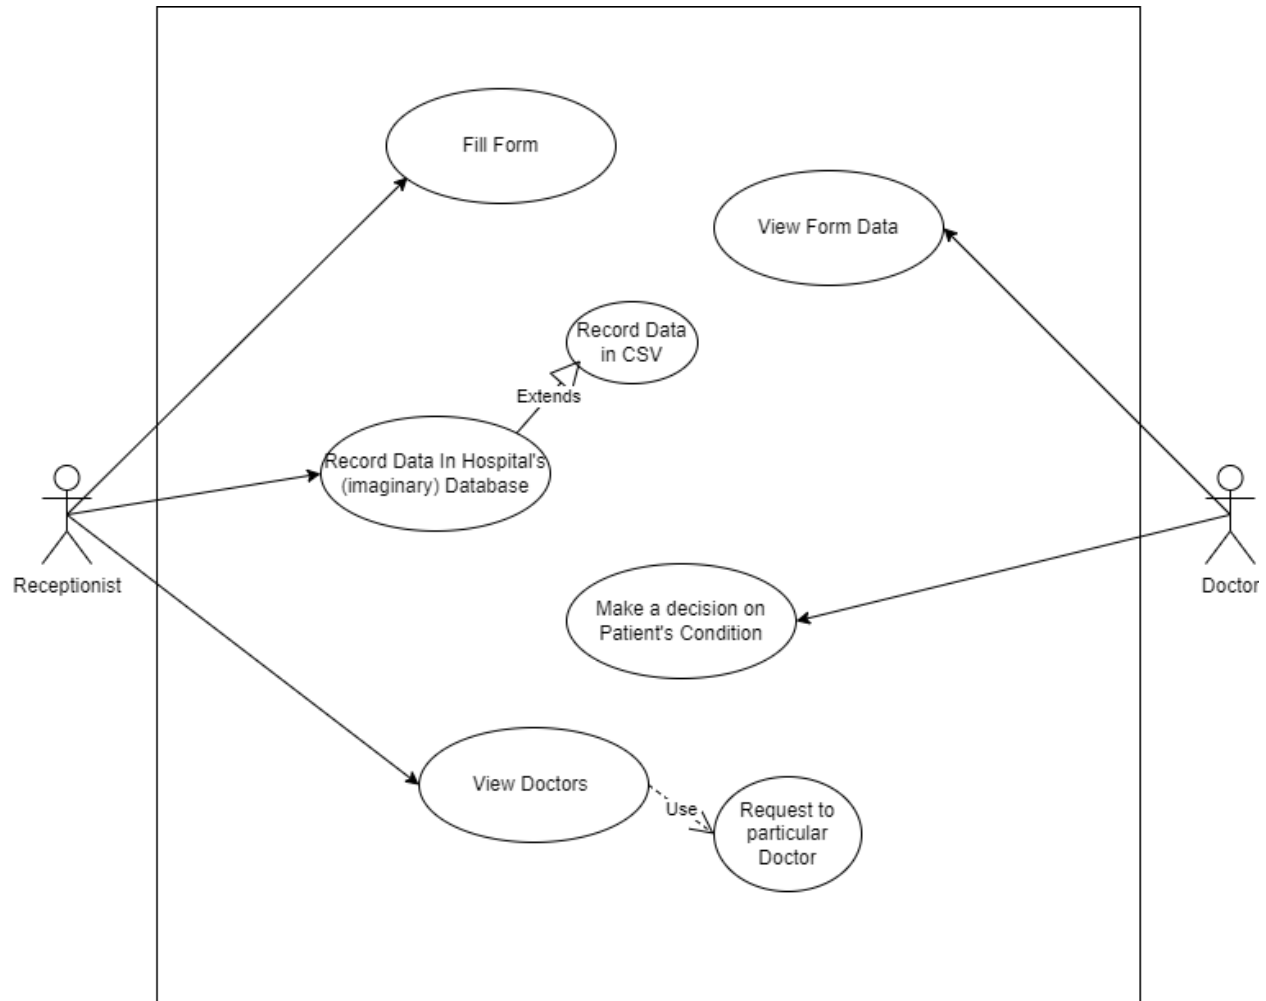

Retrieve model: super Admin can retrieve hospital model and make it interact with the global model

Aggregation of model: super admin will aggregate the model based on the weights of the different models

4.2 Use Cases

4.2.1 Form Submission

[Use Case Diagram]

Form Submission		
Use case Id:	1	
Actors:	Receptionist, Doctor	
Feature:	Submission of form	
Pre-condition:	Receptionist must be logged in and have a list of doctors Doctor should be authenticated and have a verified account given by the provider	
Scenarios		
Step#	Action	Software Reaction
1.	Fill the form of the patient	Fill input fields provided on the user interface and submit it

2.	Doctor will make a decision on the given form data and patient condition	A form view option will be visible to the doctor and he can view the patient data on the form and will make a decision accordingly for the treatment
Alternate Scenarios:		
None		
Post Conditions		
Step#	Description	
1	A final decision for the patient treatment will be taken and if the patient agrees to take part in training aggregate weights will be updated on the global server	
Use Case Cross referenced		None

4.2.2 Hospital/Superuser Use Case

[Use Case Description]

Model training	
Use case Id:	2
Actors:	Super User,Hospital
Feature:	Training of Model
Pre-condition:	SuperUser must be logged in and have access to global server model and have weights passed to it by the hospital
Scenarios	

Step#	Action	Software Reaction
1.	Hospital will register itself on the portal	Hospital will get access to take part in training of model and interacting with our system
2.	Superuser can add or remove provider from the system	Hospitals with the penalty charges or the hospital which are sucessfully registered will act accordingly
Alternate Scenarios:		
None		
Post Conditions		
Step#	Description	
1	Trained model on the recent data will be passed to the hospital and all the nodes will be updated	
Use Case Cross referenced		1

5 Non-Functional Requirements

5.1 Performance Requirement

The System shall be based on web and has to be run from a web server. The system shall take initial load time depending on internet connection strength which also depends on the media from which the product is run. The performance shall depend upon hardware components of the client/customer

5.2 Safety Requirement

The software is completely environmentally friendly and does not cause any safety violations. The web page will have a flexible font that can be zoomed so as to not over constrain the eyes.

5.3 Security Requirement

5.3.1 Data Transfer

- The system shall use secure sockets in all transactions that include any confidential customer information.
- The system shall automatically log out all customers after a period of inactivity.
- The system shall confirm all transactions with the customer's web browser.
- The system shall not leave any cookies on the customer's computer containing the user's password.
- The system shall not leave any cookies on the customer's computer containing any of the user's confidential information.

5.3.2 Data Storage

- The customer's web browser shall never display a customer's password. It shall always be echoed with special characters representing typed characters.
- The customer's web browser shall never display a customer's credit card number after retrieving from the database. It shall always be shown with just the last 4 digits of the credit card number.
- The system's back-end servers shall never display a customer's password. The customer's password may be reset but never shown.
- The system's back-end servers shall only be accessible to authenticated administrators.
- The system's back-end databases shall be encrypted.

5.4 User Documentation

The software is accompanied by the following materials for further help:

- Software Requirement Document
- Software Design Specification Document
